ABOUT THE DATASET 'TITANIC'

Variable Notes

1. pclass: A proxy for socio-economic status (SES)
   - 1st = Upper
   - 2nd = Middle
   - 3rd = Lower
2. age: Age is fractional if less than 1. If the age is estimated, is it in the form of xx.5

3. sibsp: The dataset defines family relations in this way
   - Sibling = brother, sister, stepbrother, stepsister
   - Spouse = husband, wife (mistresses and fiancés were ignored)
4. parch: The dataset defines family relations in this way
   - Parent = mother, father
   - Child = daughter, son, stepdaughter, stepson Some children travelled only with a nanny, therefore parch=0 for them.

DATA COLLECTION AND EXPLORATION

In [137…

```
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns
```

In [110…

```
# LOAD THE DATASET
data = pd.read_csv('tested.csv')
data
```

Out[110]:

FEATURE ENGINEERING

1. SibSp = Sibling/Spouse & Parch = Parent/Children

Here SibSp and Parch both are telling almost same thing so we can merge this 2 columns to 1 named as 'Total Members'

1. Here we are extracting the courtesy titles from Name column and making a new column named as 'Title'

In [119…

```
data['TotalMember'] = data['SibSp'] + data['Parch'] + 1
data['Title'] = data['Name'].str.extract(' ([A-Za-z]+)\.', expand=False)
```

In [120…

```
data.head()
```

Out[120]:

DATA SPLITTING

In [125…
```
from sklearn.model_selection import train_test_split
```

1. X = are all the independent valriables [except Survived column]
2. Y = is the dependent variable [only Survived column]

random_state in train_test_split: It controls the random shuffling and splitting of data. Setting it to a specific value ensures the same split is obtained each time for reproducibility. Different values or None produce different random splits.

In [126…
```
X = data.drop('Survived', axis=1)
Y = data['Survived']

X_train, X_test, Y_train, Y_test = train_test_split(X,Y, test_size=0.2, random_stat
```

In [127…

MODEL SELECTION AND TRAINING

Logistic regression is used here because it is a straightforward, interpretable algorithm well-suited for binary classification tasks. In this context, it helps predict whether a passenger survived (1) or not (0) based on various features. It effectively models the probability of a binary outcome.

In [131…

```
from sklearn.linear_model import LogisticRegression

logreg = LogisticRegression()
logreg.fit(X_train, Y_train)
```

```
C:\Users\Nishita Bala\anaconda3\Lib\site-packages\sklearn\linear_model\_logistic.p
y:460: ConvergenceWarning: lbfgs failed to converge (status=1):
STOP: TOTAL NO. of ITERATIONS REACHED LIMIT.

Increase the number of iterations (max_iter) or scale the data as shown in:
    https://scikit-learn.org/stable/modules/preprocessing.html
Please also refer to the documentation for alternative solver options:
    https://scikit-learn.org/stable/modules/linear_model.html#logistic-regression
  n_iter_i = _check_optimize_result(
```

Out[131]:

Logistic Regression Recall: 1.0
Logistic Regression F1 Score: 1.0
```

SOME GRAPHICAL REPRESENTATION

Confusion Matrix

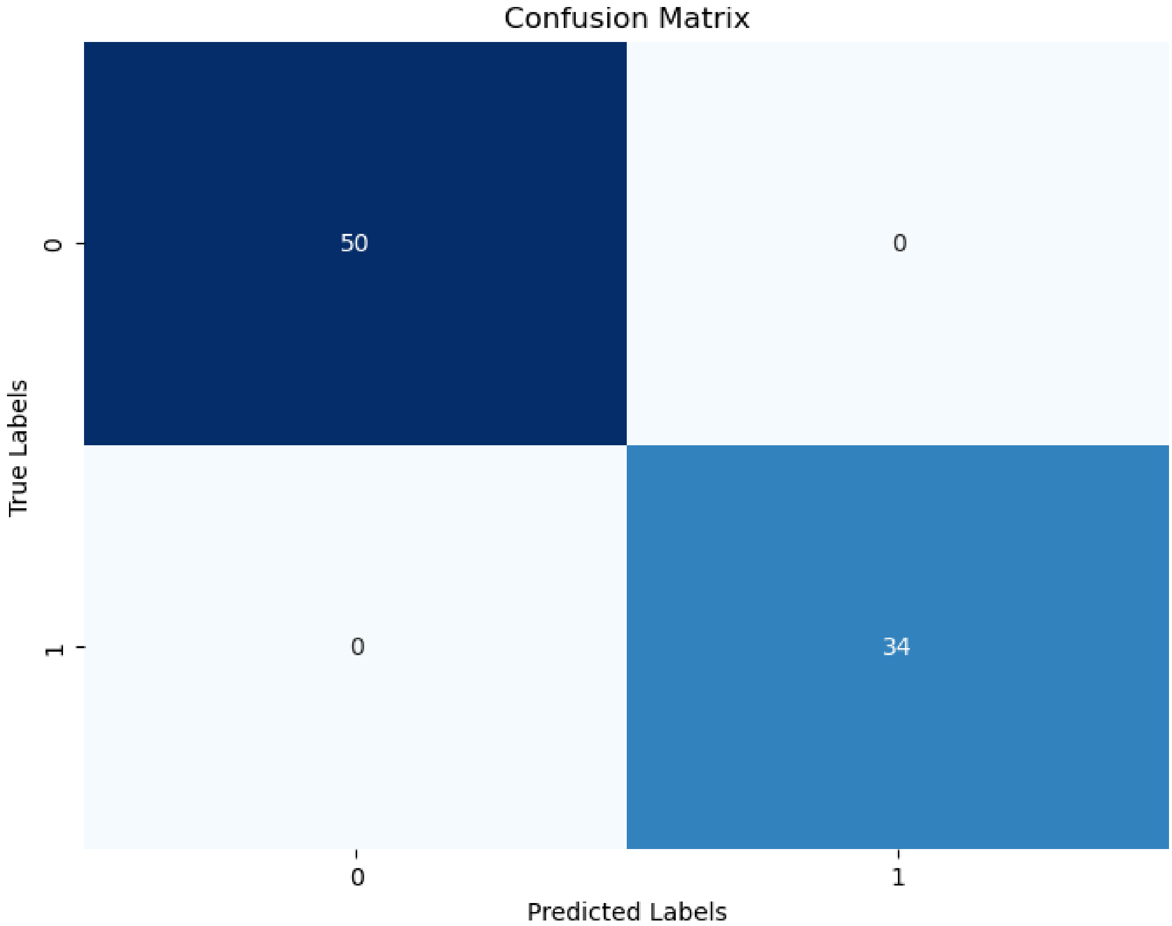
Shows the true positive, false positive, true negative, and false negative predictions of the model. Useful for understanding the model's performance in terms of correctly and incorrectly classified instances.

In [144…

```
from sklearn.metrics import confusion_matrix
conf_mat = confusion_matrix(Y_test, Y_pred)
```

In [145…

```
plt.figure(figsize=(8, 6))
sns.heatmap(conf_mat, annot=True, fmt='d', cmap='Blues', cbar=False)
plt.xlabel('Predicted Labels')
plt.ylabel('True Labels')
plt.title('Confusion Matrix')
plt.show()
```



ROC Curve

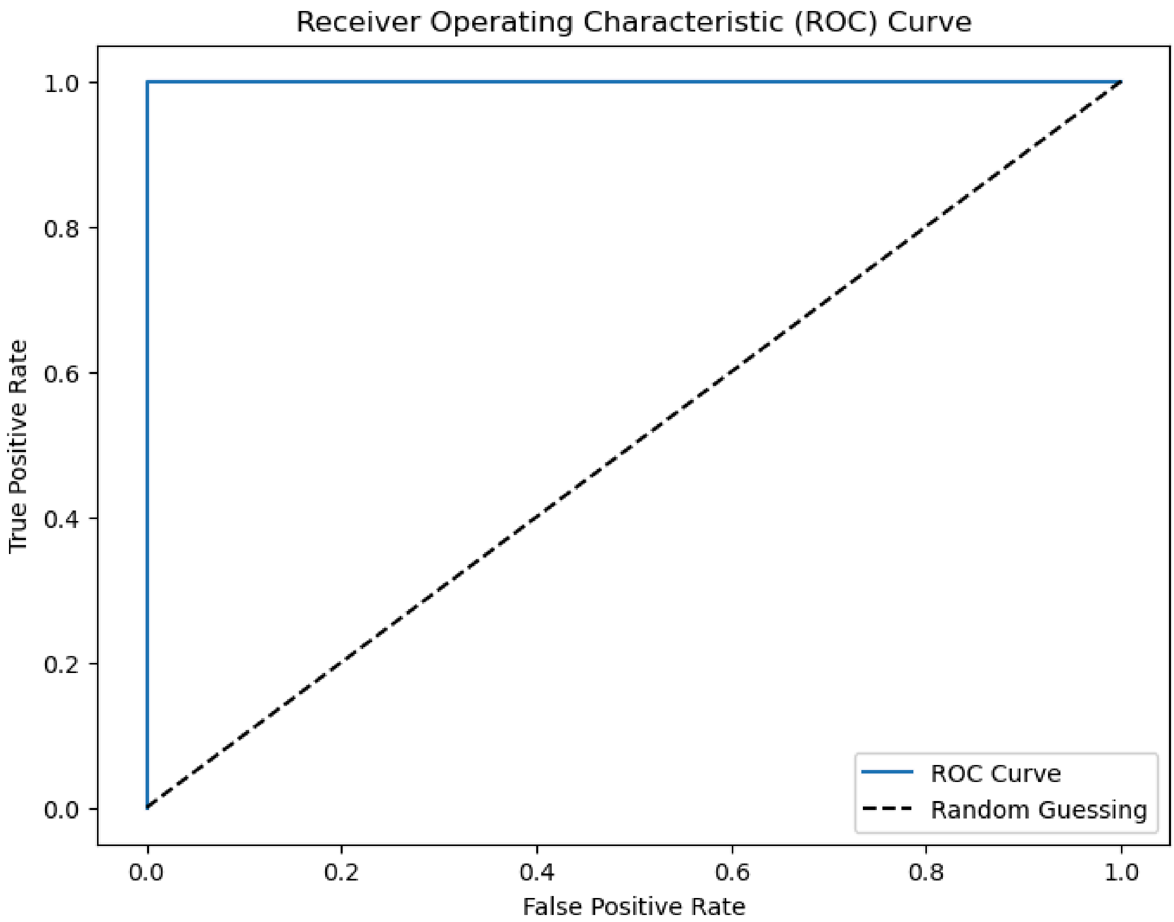
Illustrates the trade-off between sensitivity (true positive rate) and specificity (true negative rate) across different threshold values. AUC (Area Under the Curve) represents the model's ability to distinguish between positive and negative classes.

In [148…

```
from sklearn.metrics import roc_curve, roc_auc_score
Y_pred_proba = logreg.predict_proba(X_test)[:,1]
fpr, tpr, thresholds = roc_curve(Y_test, Y_pred_proba)
```

In [149…

```
plt.figure(figsize=(8, 6))
plt.plot(fpr, tpr, label='ROC Curve')
plt.plot([0, 1], [0, 1], 'k--', label='Random Guessing')
plt.xlabel('False Positive Rate')
plt.ylabel('True Positive Rate')
plt.title('Receiver Operating Characteristic (ROC) Curve')
plt.legend()
plt.show()
```



Feature Importance

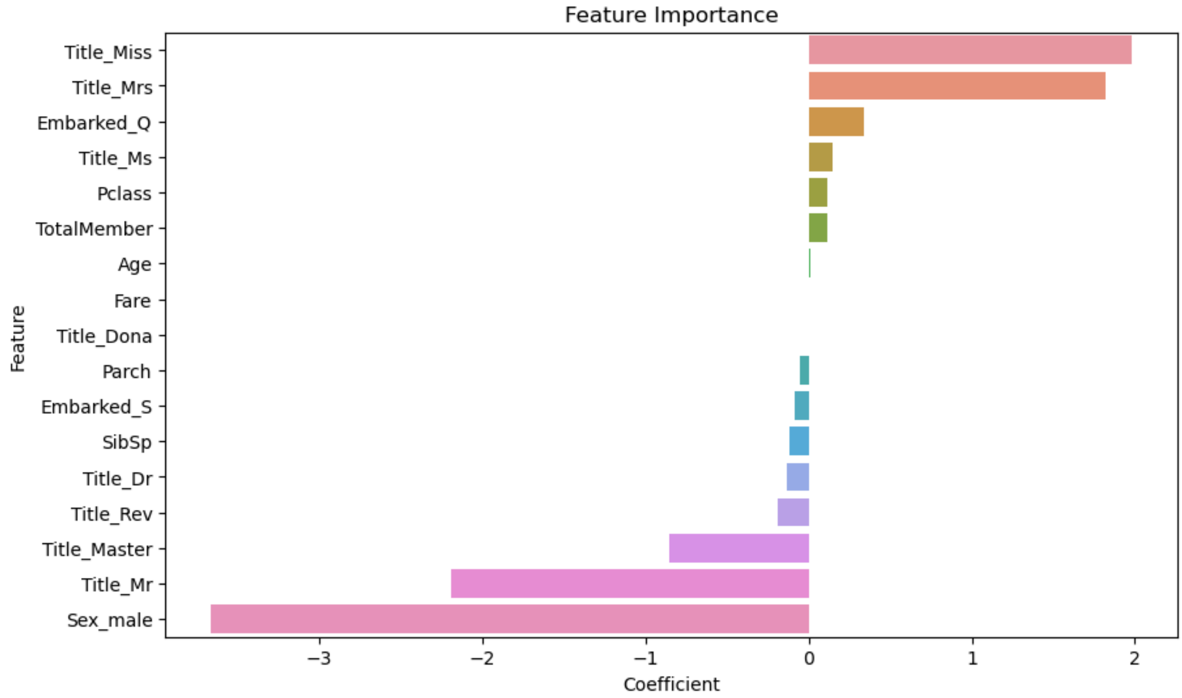
Displays the coefficients assigned to each feature by the logistic regression model. Positive coefficients indicate features that positively contribute to survival probability, while negative coefficients indicate features that negatively contribute.

In [150…

```
coef = logreg.coef_[0]
features = X.columns
feature_importance_df = pd.DataFrame({'Feature': features, 'Coefficient': coef})
feature_importance_df = feature_importance_df.sort_values(by='Coefficient', ascendi
```

In [151…

```
plt.figure(figsize=(10, 6))
sns.barplot(x='Coefficient', y='Feature', data=feature_importance_df)
plt.xlabel('Coefficient')
plt.ylabel('Feature')
plt.title('Feature Importance')
plt.show()
```



CONCLUSION

- Socio-Economic Status: Features like fare price and class may have a significant positive impact on survival, as suggested by their positive coefficients in the feature importance plot.
- Age: Younger passengers may have a higher chance of survival, as indicated by the positive coefficient for age.
- Gender: Being female likely increases the likelihood of survival, as indicated by the positive coefficient for the 'Sex_male' feature.
- These visualizations and analysis provide insights into the factors influencing survival on the Titanic and help in building a system to predict survival likelihood.
